

## Overview

The Open Core Protocol (OCP) establishes the first *openly licensed, core-centric protocol* to meet contemporary system-level integration challenges. OCP comprehensively defines an efficient, bus-independent, configurable and highly scalable interface for on-chip subsystem communications. With broad industry support and collaboration, OCP International Partnership (OCP-IP) now offers the 2.2 version specification that further extends capabilities in increasingly important areas such as very high performance multithreading, synchronization primitives and single-request/multiple-data transactions. OCP data transfer models range from simple request-grant handshaking through pipelined request-response to complex out-of-order operations.

Legacy IP cores are readily adapted to OCP, while new implementations may take full advantage of advanced features: designers select only those features and signals encompassing a core's specific data, control and test configuration. Core definition using OCP encapsulates a complete system integration description enabling *core and test bench reuse without rework*. Not only does OCP provide clear delineation of design responsibilities for core authors and System-on-Chip (SoC) integrators, but also institutes a key partitioning formalism for verification engineers and automation software.

## Highlights

The OCP promotes IP core reusability and reduces design time, design risk and manufacturing costs for SoC designs. It focuses exclusively on IP core interfacing without pre-empting interconnect topology or other application-specific integration choices.

- Enables IP core creation to be independent of system architecture and application domain
- Describes all inter-core communications
- Optimizes die area by configuring into the OCP interface only those features needed by the core
- Specified timing categories assure core interoperability
- Facilitates rapid, plug-and-play IP integration

## Advantages

- The *de facto* open standard with industry wide support
- Eliminates the ongoing task of interface protocol (re)definition, verification, documentation and support
- Readily adapts to support new core capabilities
- Testbench portability simplifies (re)verification
- Limits test suite modifications for core enhancements
- Interfaces to any bus structure or on-chip network
- Delivers industry-standard flexibility and reuse
- Point-to-point protocol can directly interface two cores

## Capabilities

The OCP captures all core characteristics without restricting system arbitration, address map, etc.

- Small set of mandatory signals, with a wide range of optional signals
- Synchronous, unidirectional signaling allows simplified implementation, integration and timing analysis
- Configurable address and data word width
- Structured method for inclusion of sideband signals: high-level flow control, interrupts, power control, device configuration registers, test modes, etc.
- Transfers may be *pipelined* to any depth for increased throughput
- Optional burst transfers for higher efficiency
- Multiple concurrent transfers use *thread identifiers* for out-of-order completion
- *Connection identifiers* provide end-to-end traffic identification for differential quality of service, etc.
- Synchronization primitives include atomic test-set, lazy synchronization, non-posted write commands
- OCP is a functional superset of the VSIA's Virtual Component Interface (VCI) adding protocol options that include configurable sideband signaling and test harness signals

**Complete spectrum of core signaling can be handled by a single protocol – the OCP**
